

# IMPORTANT QUESTIONS CLASS – 12

## PHYSICS CHAPTER – 13 NUCLEI

---

### Question 1.

Calculate the binding energy per nucleon of  $\text{Fe}^{56}_{26}$  Given  $m_{\text{Fe}} = 55.934939 \text{ u}$ ,  $m_n = 1.008665 \text{ u}$  and  $m_p = 1.007825 \text{ u}$

Answer:

Number of protons  $Z = 26$

Number of neutrons  $(A - Z) = 30$

Now mass defect is given by

$$\Delta m = Z m_p + (A - Z)m_n - M$$

$$\begin{aligned}\Delta m &= 26 \times 1.007825 + 30 \times 1.008665 - 55.934939 \\ &= 0.528461 \text{ u}\end{aligned}$$

Therefore binding energy

$$\begin{aligned}\text{BE} &= \Delta m \times 931 \text{ MeV} = 0.528461 \times 931 \\ &= 491.99 \text{ MeV}\end{aligned}$$

$$\text{BE/nucleon} = 491.99/56 = 8.785 \text{ MeV}$$

### Question 2.

The activity of a radioactive element drops to one-sixteenth of its initial value in 32 years. Find the mean life of the sample.

Answer:

$t = 32$  years,  $A = A_0 / 16$ , using

$$A = A_0 \left(\frac{1}{2}\right)^n \text{ where } n = t / T \text{ we have}$$

$$\frac{A_0}{16} = A_0 \left(\frac{1}{2}\right)^{32/T}$$

$$\left(\frac{1}{2}\right)^4 = \left(\frac{1}{2}\right)^{32/T}$$

Or

$$32/T = 4 \text{ or } T = 32 / 4 = 8 \text{ years.}$$

Therefore mean life of the sample is  $\tau = 1.44 T = 1.44 \times 8 = 11.52$  years.

### Question 3.

A radioactive sample contains 2.2 mg of pure  $^{116}\text{C}$  which has a half-life period of 1224 seconds. Calculate (i) the number of atoms present initially and (ii) the activity when 5 pg of the sample will be left.

Answer:

Mass of sample = 2.2 pg

Now 11 g of the sample contains  $6.023 \times 10^{23}$  nuclei, therefore the number of nuclei in 2.2 mg =  $2.2 \times 10^{-3}$  g are

$$2.2 \text{ mg} = 2.2 \times 10^{-3} \text{ g are}$$

$$\frac{6.023 \times 10^{23}}{11} \times 2.2 \times 10^{-3} = 1.2 \times 10^{20}$$

Given  $T = 1224$  s.  
Number of nuclei in 5  $\mu\text{g}$

$$N = \frac{6.023 \times 10^{23}}{11} \times 5 \times 10^{-6} = 2.7 \times 10^{17}$$

#### Question 4.

The half-life of  $^{238}_{92}\text{U}$  is  $4.5 \times 10^9$  years.

Calculate the activity of 1 g sample of  $^{238}_{92}\text{U}$ .

Answer:

Given  $T = 4.5 \times 10^9$  years.

Number of nuclei of U in 1 g

$$= N = 6.023 \times 10^{23} \times \frac{1}{238} = 2.5 \times 10^{21}$$

Therefore activity

$$A = \lambda N = \frac{0.693}{T} \times N = \frac{0.693}{4.5 \times 10^9} \times 2.5 \times 10^{21}$$

$$= 3.85 \times 10^{11} \text{ dis } y^{-1}$$

#### Question 5.

The decay constant for a given radioactive sample is 0.3456 per day.

What percentage of this sample will get decayed in a period of 4 days?

Answer:

Given  $\lambda = 0.3456 \text{ day}^{-1}$

or

$$T_{1/2} = 0.693/\lambda = 0.693/0.3456 = 2.894 \text{ days, } t = 4 \text{ days.}$$

Let  $N$  be the mass left behind, then  $N = N_0 e^{-\lambda t}$

or

$$N = N_0 e^{-0.3456 \times 4}$$

or

$$N = N_0 e^{-1.3824} = N_0 \times 0.25$$

$$\frac{N_0 - N}{N_0} \times 100 = \frac{N_0 - 0.25N_0}{N_0} \times 100$$

$$= 75 \%$$

Therefore the percentage of undecayed is

#### Question 6.

It is observed that only 6.25 % of a given radioactive sample is left undecayed after a period of 16 days. What is the decay constant of this sample per day?

Answer:

Given  $N/N_0 = 6.25 \%$ ,  $t = 16$  days,  $\lambda = ?$

Or

$$16/T = 4 \text{ or } T = 4 \text{ days.}$$

$$\frac{N}{N_0} = 6.25 \% = \frac{1}{16}$$

Using the relation  $N = N_0 \left(\frac{1}{2}\right)^n$  we have

$$\frac{N}{N_0} = \left(\frac{1}{2}\right)^{16/T} \text{ or}$$

$$\left(\frac{1}{16}\right) = \left(\frac{1}{2}\right)^{16/T} \text{ or } \left(\frac{1}{2}\right)^4 = \left(\frac{1}{2}\right)^{16/T}$$

Therefore  $\lambda = 1/T = 1/4 = 0.25 \text{ day}^{-1}$

### Question 7.

**A radioactive substance decays to  $1/32^{\text{th}}$  of its initial value in 25 days. Calculate its half-life.**

Answer:

Given  $t = 25$  days,  $N = N_0 / 32$ , using

$$N = N_0 \left(\frac{1}{2}\right)^n \text{ where } n = t / T \text{ we have}$$

Or

$25/7 = 5$  or  $T = 25 / 5 = 5$  days.

$$\frac{N_0}{32} = N_0 \left(\frac{1}{2}\right)^{25/T} \text{ or } \left(\frac{1}{2}\right)^5 = \left(\frac{1}{2}\right)^{25/T}$$

### Question 8.

**The half-life of a radioactive sample is 30 s.**

**Calculate**

**(i) the decay constant, and**

Answer:

Given  $T_{1/2} = 30$  s,  $N = 3N_0 / 4$ ,  $\lambda = ?$ ,  $t = ?$

(i) Decay constant

$$\lambda = 0.693/T_{1/2} = 0.693/30 = 0.0231 \text{ s}^{-1}$$

**(ii) time taken for the sample to decay to  $3/4$  th of its initial value.**

Answer:

Using  $N = N_0 e^{-\lambda t}$  we have

$$\begin{aligned} \frac{3N_0}{4} &= N_0 e^{-\lambda t} \text{ or } \ln \frac{4}{3} = \lambda t \text{ or} \\ t &= \frac{2.303 \log 1.333}{\lambda} \\ &= \frac{2.303 \log 1.333}{0.0231} = 12.49 \text{ s} \end{aligned}$$

### Question 9.

**The half-life of  $^{14}\text{C}$  is 5700 years. What does it mean?**

**Two radioactive nuclei X and Y initially contain an equal number of atoms. Their half-lives are 1 hour and 2 hours respectively. Calculate the ratio of their rates of disintegration after 2 hours.**

Answer:

It means that in 5700 years the number of nuclei of carbon decay to half their original value.

Given  $N_{0X} = N_{0Y}$ ,  $T_X = 1$  h,  $T_Y = 2$  h, therefore

$$\lambda_X \lambda_Y = 21 = 2$$

Now after 2 hours X will reduce to one-fourth and Y will reduce to half their original value.

If activities at  $t = 2$  h are  $R_X$  and  $R_Y$  respectively, then

Thus their rate of disintegration after 2 hours is the same.

$$\frac{R_X}{R_Y} = \frac{\lambda_X}{\lambda_Y} \times \frac{N_X}{N_Y} = 2 \times \frac{(N_0)_X / 4}{(N_0)_Y / 2} = 1$$

**Question 10.**

**A star converts all its hydrogen to helium achieving 100% helium composition. It then converts helium to carbon via the reaction.**

**The mass of the star is  $5 \times 10^{32}$  kg and it generates energy at the rate of  $5 \times 10^{30}$  watt.**

**How long will it take to convert all the helium to carbon at this rate?**

Answer:

As  $4 \times 10^{-3}$  kg of He consists of  $6.023 \times 10^{23}$  He nuclei so  $5 \times 10^{32}$  kg He will contain  $6.023 \times 10^{23} \times 5 \times 10^3 \times 10^{-3} = 7.5 \times 10^{58}$  nuclei

Now three nuclei of helium produce  $7.27 \times 1.6 \times 10^{-13}$  J of energy

So all nuclei in the star will produce

$$E = 7.27 \times 1.6 \times 10^{-13} \times 7.5 \times 10^{58}$$

$$= 2.9 \times 10^{46} \text{ J}$$

As power generated is  $P = 5 \times 10^{30}$  W, therefore time taken to convert all He nuclei into carbon is

$$t = \frac{E}{P} = \frac{2.9 \times 10^{46}}{5 \times 10^{30}} = 5.84 \times 10^{15} \text{ s}$$

or

$$1.85 \times 10^8 \text{ years}$$
